Abstract

Gaussian curvature is commonly seen in the study of differential geometry. Gaussian curvature of a surface at a point is the product of the principal curvatures. They measure how the surface bends by different amounts in different directions at the point. Also, Gaussian curvature is given as the determinant of shape operator. In pure mathematics, differential equations are studied from different viewpoints. There are a lot of methods for solving differential equations in mathematics. From the differential equations viewpoint, Gaussian curvature solves the differential equation to find the main curve. One of them is Chebyshev expansion method by using Chebyshev polynomials. Also, they are important study in approximation theory. Chebyshev polynomials are a sequence of orthogonal polynomials and compose a polynomial sequence. The series solution is also used in surface of revolution. A surface of revolution is a surface generated by rotating a two-dimensional curve. In this study, our aim is to find the main curve by using Gaussian curvature. We substitute solution into the differential equation to find a relation for coefficients of system. So, we use Chebyshev polynomials for solutions to determine the curve and demonstrate our results on some well-known surfaces such as sphere, catenoid and torus.

1 Introduction

In differential geometry, the Gaussian curvature \( \kappa \) of a surface at a point is the product of the principal curvatures \( k_1 \) and \( k_2 \):

\[
\kappa = k_1 k_2.
\]

At a point \( p \) on surface in \( IR^3 \), the Gaussian curvature is also given by

\[
\kappa(p) = \det S(p),
\]

where \( S \) is the shape operator \([2,3,4,6]\). Also, Gaussian curvature solves the differential equation to find the main curve.

In mathematics, there are a lot of methods for solving differential equations. One of them is Chebyshev expansion method by using Chebyshev polynomials. The Chebyshev polynomials are polynomials of degree \( n \) \([1]\). The Chebyshev polynomials of the first kind are defined by

\[
T_0(x) = 1, \quad T_1(x) = x,
\]

\[
T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x).
\]

A surface of revolution can be obtained by rotating a curve in the \( xz \)-plane about the \( z \)-axis. Suppose that the curve is given by

\[
x = \varphi(t), \quad z = \psi(t)
\]

with \( t \) lies in \((a, b)\), and is parametrized by arclength, so that

\[
\dot{\varphi}^2 + \dot{\psi}^2 = 1
\]

(1)

The coefficients of first fundamental form are given by

\[
E = \varphi^2, \quad F = 0, \quad G = (\dot{\varphi})^2 + (\dot{\psi}).
\]

The coefficients of second fundamental form are given by

\[
e = \varphi \psi, \quad f = 0, \quad g = \dot{\psi} \ddot{\varphi} - \dot{\varphi} \dot{\psi}.
\]

Then, we obtain

\[
\kappa(t) = \frac{eg - f^2}{EG - F^2} = \frac{\dot{\varphi} \ddot{\psi} - \dot{\psi} \ddot{\varphi}}{\varphi}
\]

If we differentiate equation (1), we find

\[
\dot{\varphi} = -\psi \dot{\psi} \quad (2)
\]

After some calculations, we get

\[
K(t) = -\frac{\ddot{\varphi}}{\varphi}. \quad (3)
\]
Our aim is to find the curve $\varphi$ by using Chebyshev polynomials. Then, we substitute solution into the differential equation to find relation for the coefficients. The results are applied on some well-known surfaces such as sphere, catenoid and torus.

2 Method

\[ \varphi + K(x) \varphi = 0 \quad (4) \]

If we substitute $\varphi = \sum_{n=0}^{\infty} A_n T_n(x)$, $\varphi' = \sum_{n=1}^{\infty} n A_n (T_n(x))'$ and $\varphi'' = \sum_{n=2}^{\infty} n(n-1) A_n (T_n(x))''$ into equation (4), we obtain

\[ \sum_{n=2}^{\infty} A_n (T_n(x))'' + K(x) \sum_{n=0}^{\infty} A_n T_n(x) = 0 \quad (5) \]

After some calculations [7,8,9], we obtain

\[
\begin{align*}
A_2 &= -\frac{k(x) A_0}{4} \\
A_3 &= -\frac{k(x) A_1}{24} \\
A_4 &= \frac{(2x^2 - 1) k^2 (x) A_0}{4(96x^2 - 16)}
\end{align*}
\]

Hence, we can find the coefficients of $\varphi$.

\[ \varphi = A_0 T_0(x) + A_1 T_1(x) + A_2 T_2(x) + A_3 T_3(x) + A_4 T_4(x) + \ldots \quad (6) \]

Finally, we obtain

\[ \varphi = \frac{1}{\pi} \int_{-1}^{1} x \varphi(x) dx \quad (1 - \frac{k(x)}{4} + \frac{(2x^2 - 1) k^2 (x)}{4(96x^2 - 16)} + \ldots) + \frac{2}{\pi} \int_{-1}^{1} x \varphi(x) dx \quad (x - \frac{k(x)}{24} + \frac{(4x^2 - 3) k^2 (x)}{320x^2 - 120} + \ldots). \quad (7) \]

3 Examples

The Gaussian curvature of paraboloid which has radius $a$ at height $h$ is

\[ K(x) = \frac{4h^2}{(a^2 + 4hx^2)} \quad (8) \]

We can find that

\[ \varphi = \frac{1}{\pi} \int_{-1}^{1} \frac{\varphi(x) dx}{\sqrt{1-x^2}} \quad (1 - \frac{h^2}{(a^2 + 4hx)} + \frac{(2x^2 - 1) h^2}{(a^2 + 4hx)(96x^2 - 16)} + \ldots) + \frac{2}{\pi} \int_{-1}^{1} x \varphi(x) dx \quad (x - \frac{h^2}{6(a^2 + 4hx)} + \frac{(4x^2 - 3) h^2}{320x^2 - 120} + \ldots). \quad (9) \]

The Gaussian curvature of paraboloid which has the radius from the center of the hole to the center of the torus tube and the radius of the tube be $a$ is

\[ K(x) = \frac{\cos x}{a(e^x + a \cos x)} \quad (10) \]

We can find that

\[ \varphi = \frac{1}{\pi} \int_{-1}^{1} \frac{\varphi(x) dx}{\sqrt{1-x^2}} \quad (1 - \frac{\cos x}{4a(e^x + a \cos x)} + \frac{4a^2(c + a \cos x)}{(2x^2 - 1) \cos x} + \ldots) + \frac{2}{\pi} \int_{-1}^{1} x \varphi(x) dx \quad (x - \frac{\cos x}{(4x^2 - 3) \cos x} + \frac{32a(e^x + a \cos x)}{(120x^2 - 120)(e^x + a \cos x)} + \ldots). \quad (11) \]

The Gaussian curvature of catenoid is [5]

\[ K(x) = -\frac{1}{e} \sinh^2 \frac{x}{e} \quad (12) \]

We can find that

\[ \varphi = \frac{1}{\pi} \int_{-1}^{1} \frac{\varphi(x) dx}{\sqrt{1-x^2}} \quad (1 + \frac{\sinh^2 x}{4e} + \frac{2(2x^2 - 1) \sinh^2 x}{496x^2 - 16} + \ldots) + \frac{2}{\pi} \int_{-1}^{1} x \varphi(x) dx \quad (x + \frac{\sinh^2 x}{24e} + \frac{(4x^2 - 3) \sinh^2 x}{320x^2 - 120} + \ldots). \quad (13) \]
