ABSTRACT
Pharmacists are supposed to know current issues in social sciences and techniques to understand diseases and illnesses, to empathize with patients and other health professionals, to resolve possible conflicts of interest, to establish an ideal communication, to ensure the rational use of drugs, to reduce the wastage of drugs, and to improve compliance with drug therapy. The purpose of this article was to explain the conceptual framework of the Health Belief Model and Functional Health Literacy, which are recently outstanding topics on healthcare. Further, Pharmacotherapy Literacy is going to be defined as a remarkable subject in the literature. This is a descriptive study illustrating the concepts with the literature.

Keywords: Health beliefs, health literacy, pharmacotherapy literacy, public health

INTRODUCTION
Health Belief Model (HBM) has been developed by Hochbaum, Leventhal, Rosenstock and Kegeles in 1959, the United States of America, in response to the failure of a free or very low-paid Pap smear testing which was early detection of cervical cancer or Tuberculosis screening immunization program as important public health problem (Haefner and Kirscht 1970; Rosenstock 1974). Since then, HBM has been adapted to explain the relationship between beliefs and behavior of individuals about health and illness (Avcı, 2014).

Components of the HBM
There are six components of the model (Figure 1, Rosenstock et al. 1988; Çenesiz and Atak, 2007).

Perceived sensitivity: the perception of the disease that threaten the health of people; acceptance of the diagnosis, the probability of getting the disease.

Perceived severity: results will occur when the treatment not to be admitted; death, disease, disability, pain include assessment of the possible consequences, such as social losses. If the sensitivity and seriousness are taken together, this is defined as the Perceived threat.

Perceived benefits: due to perform behavior was perceived benefits associated with a reduced risk of developing the disease. People think that preventive health behaviors will give him/her the benefit. This benefit is expected to decrease the risk of developing the disease.

Perceived barriers: barriers to the realization of the proposed believed to difficult behavior or the potential negative aspects of the behavior. People weigh the positive and negative consequences of the behavior. The behavior is performed if perceived

susceptibility, severity and benefits reduce the impact of perceived barriers.

In other words, perception of health-related protective factors that prevent or make it difficult to perform a behavior. The most important variables that prevent the realization of protective health behaviors is the difference between the perceived benefits and perceived barriers.

Self-efficacy: one of the components of Albert Bandura's Social Cognitive Theory involves the person's self-belief, determination, self-control related the realization of behavior in order to achieve expected results. This component was added later to the model. Therefore, self-efficacy plays an important role in sustaining the introduction of changes in behavior and attitude.

For a better understanding of well-being, health concept is examined in two dimensions (Figure 2, Birol 2004). When considering the dimensions of health, the issue of health beliefs deserves special attention.

Belief areas that should be primarily discussed (Matthews and Hingson 1977)

A- Beliefs about the disease itself
This area include the beliefs of the seriousness of the disease and beliefs regarding the possibility of perceptual suffering from those in the future.

Beliefs can be released with some questions;
1- Why are you worried about high blood pressure?
2- How do you think about your pain now?
3- What do you think about the source of the problem you identify?
4- Do you know one who has cancer like you?

B- Beliefs regarding the benefits
The model evaluates patient's decision about the acceptance of a treatment plan in terms of cost-benefit analyzes. Many patients who perceive significant cost associated with the treatment plan, are at risk of becoming poorly compatible while rejecting the slightest benefits of treatment. These costs sometimes means different things for the patient in finance (Figure 3).

The questions that would release the beliefs
1- What are you doing to yourself for your pain?
2- Do you think there might be any problems with these drugs when taken 1 hour before meals?
3- While monthly blood test, is there something bothering you?
4- Have you worried about side effects of this medicine?

The questions that would reveal benefits
1- Injections, how long do you think it would be dangerous for you?
2- If you forget to take their medication for a night, what do you think would happen?

Knowledge of health beliefs is important in terms of detecting the risk places of poor adherence patients and increasing patient compliance (Figure 4). Beliefs can be changed in important measure by each patient's visit. Health care workers are not the only source of health information for patients. Friends, relatives, magazines, mass communication-media, the diagno-
skills as reading medicine bottles and other materials related to the constellation of skills involving performing such basic reading and numerical calculations. The American Medical Association (AMA) is that “Basic skills in reading, writing and ‘numercy’ are especially important in the healthcare setting, where patient participation in planning and implementing therapeutic regimens is critical for success” (Parker et al. 1995).

Pharmacotherapy Literacy

The definition of Pharmacotherapy Literacy was developed by King et al. because of the complex nature of the pharmacy-patient encounter. Pharmacotherapy Literacy is “An individual’s ability to obtain, evaluate, calculate, comprehend and properly act upon patient-specific information concerning pharmacotherapy and pharmaceutical services necessary to make appropriate medication-related decisions, regardless of the mode of content delivery (e.g. written, oral, visual images and symbols)” (King et al. 2011).

CONCLUSION

Today, health care is located in a complex point where advanced technological developments in the health dimension are settled. The role of patients as consumers and individuals are intertwined. Also the individual’s functionally health literacy in such a dynamic system is important. Individuals must be strengthened in this dynamic system by developing the health beliefs and functional health literacy which are important motivation in improving the health status of the community are critical scientific research topics. According to the scientific literature, health differences levels in community would be reduced by increasing the functional health literacy (Aslantekin and Yumrutaş 2014).

If one was identified as health illiterate, pharmacist would provide an education in terms of drugs. This education includes the use of both education aids and oral counseling methods to achieve the best outcomes of drug therapy (Tcakz et al. 2008). However, when we look at the scientific research conducted on the subject in the European Union between 1991-2005, Turkey ranks 14th with a total of 492 research (Sağlık Bakanlığı 2014). Eventually, first large-scale field research was applied by Sağlık Sen in 2014, Turkey (Sağlık Sen, 2014). According to the summary findings of this study;

- General health literacy index averaged over a 50-point scale was calculated as 30.4. The average index is 33.8 in Europe and the difference is significant. It is pointed out that 64.6% has insufficient or problematic health literacy. This figure corresponds to an adult population of 35 million. In other words, only 35.4% of the community has enough or excellent health literacy. This ratio is 52.5% in the European study.
- 51.7% of the population stated that they use drugs without medical advice or prescription.
It has been shown that while the age is increasing and education level decreasing, health literacy linearly decreased. Considering the results of the large scale research applied in Turkey, pharmacist can play a vital role in order to recognize the low health literacy or pharmaceutical literacy (Butler et al. 2013). According to a study focusing on glaucoma control has found that the level of medication adherence has been positively related to health literacy (Muir et al. 2006).

Pharmacists as one of the most accessible providers (Kehoe and Katz 1998) are supposed to be a part of the process of determining health illiterate patient in order to success the aimed results of drug therapy, especially when the half of the population use drugs without medical advice or prescription. Therefore pharmacy education curriculum or courses provided should include critical social subjects mentioned in the article.
