Ferulic Acid Substituted Zn(II) Phthalocyanine: Synthesis, Characterization and Investigation of Photophysical and Photochemical Properties

Semih Gorduk

Yildiz Technical University, Faculty of Arts and Science, Department of Chemistry, 34210, Istanbul, Turkey.

Abstract: In this study, novel peripherally ferulic acid tetra-substituted Zn(II) phthalocyanine was synthesized for the first time. The synthesized phthalocyanine was characterized by elemental analysis, infrared spectroscopy, UV-Vis spectrophotometry, 1H-NMR spectroscopy, and MALDI-TOF MS techniques. The photophysical, photochemical and aggregation properties of this phthalocyanine were also investigated in DMSO and DMF solvents. The aggregation studies showed that the synthesized Zn(II) phthalocyanine does not aggregate in DMSO and DMF. Fluorescence quantum yield (ΦF: 0.23 in DMSO and 0.17 in DMF), singlet oxygen quantum yield (Φ1: 0.57 in DMSO and 0.45 in DMF) and photodegradation quantum yield (Φd: 1.08x10^-5 in DMSO and 4.44x10^-4 in DMF) were also determined. These results show that the synthesized phthalocyanine has potential use in photodynamic therapy.

INTRODUCTION

In the recent years, phthalocyanines (Pcs) have been comprehensively studied by scientists due to their unique chemical, physical, optical and structural properties such as aromatic 18-π conjugated electron systems, very versatile and stable aromatic macrocyclic ring, strong and long-wavelength absorption, high thermal stability, chemical resistance, photoconductivity, and catalytic activity (1-3). Because of these properties, Pcs have been used in many applications. For example, catalysis (4), liquid crystals (5), chemical sensors (6), semiconductor materials (7), photovoltaics (8), electrochemistry (9, 10), photodynamic therapy (PDT) (11) are important areas in which Pcs are used. In particular, metallo Pcs can absorb at high wavelength lights near the red region of light. With this feature, they are used in photodynamic therapy as photosensitizers suitable for cancer treatment studies (12).

Photodynamic therapy (PDT) is a process in which compounds called photosensitizers absorb light in a specific wavelength, lower energy triplet into a high energy singlet and thus causing the destruction of the cancerous cells in the area where the photosensitizers are located (13). Pcs exhibit photosensitizer properties (14). Pcs containing diamagnetic metal ions (Zn, Ga, In, Si) are photoactive and are usually utilized in PDT due to their high efficiency of cytotoxic singlet oxygen photogeneration and long triplet lifetimes (15, 16). However, Pcs have disadvantage such as insolubility in common organic solvents. The use of Pcs is limited due to this disadvantage. Alkyl, alkoxy/alkylthio, sulfonyl, carboxyl and quaternized ammonium groups may be used in peripheral and non-peripheral positions to overcome this disadvantage (17-19). Especially, carboxylic acid groups are particularly useful to acquire solubility in common organic solvents and water (20-22). There are many studies in the literature that include carboxylic acid groups to increase solubility and prevent aggregation (23).
For example, ZnPc bearing 16-carboxylic acid groups was reported by M. Liu et al. (2005) to diminish aggregation for utilize as a potential photosensitizer for PDT (24). M.-R. Ke et al. (2009) synthesized non-peripherally and peripherally tetra-substituted with carboxylic acid zinc(II) Pcs as photosensitizers (25). Beta and alpha tetra-[4-oxy-3-methoxybenzoic acid]-substituted Zn(II), Co(II) and Cu(II) Pcs were reported by G. Özgül et al. (2015) for comparative electrochemistry studies (26).

Herein, we reported synthesis and characterization of ferulic acid functionalized peripherally tetra-substituted Zn(II) phthalocyanine. Zinc(II) Pcs have a high singlet oxygen quantum yield and thus they were studied as photosensitizers for PDT. For this reason, we investigated the aggregation, photophysical and photochemical properties of the Zn(II) phthalocyanine synthesized here. Fluorescence quantum yield, singlet oxygen quantum yield and photodegradation quantum yield indicate that this compound is a potential photosensitizer in the PDT.

**MATERIALS AND METHODS**

**Chemical and Reagents**

Trans-ferulic acid (trans-4-hydroxy-3-methoxycinnamic acid), 4-nitrophthalonitrile, zinc(II) acetate, 1,3-diphenylisobenzofuran (DPBF), potassium carbonate (K₂CO₃), and 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) were purchased from Sigma-Aldrich and TCI chemical companies. All chemicals and solvents were acquired with high purity from commercial suppliers. All solvents were dried and stored over molecular sieves.

**Equipments**

\[ \Phi_F = \Phi_{F(\text{Std})} \frac{F . A_{\text{Std}} . n^2}{F_{\text{Std}} . A . n_{\text{Std}}^2} \]

Where \(F\) and \(F_{\text{Std}}\) are the areas under the fluorescence emission curves of the sample (The synthesized phthalocyanine) and the standard, respectively. \(A\) and \(A_{\text{Std}}\) are the respective absorbances of the sample and standard at the excitation wavelengths. \(n\) and \(n_{\text{Std}}\) are the refractive indices of solvents used for the samples and standard, respectively.

**Singlet oxygen quantum yield determination**

Singlet oxygen quantum yield (\(\Phi_{\Delta}\)) determinations were carried out using the experimental setup described in the literature (22, 23, 31) with standard unsubstituted Zn(II) phthalocyanine (in DMSO and DMF) as the reference. Typically, a 2 mL portion of the zinc(II) phthalocyanine solution (\(C = 1.0 \times 10^{-5}\) M) that contained the singlet oxygen scavenger was irradiated in the Q-band region with the photoirradiation setup described in the literature. The \(\Phi_{\Delta}\) values were determined in air using the relative method with DPBF as a singlet oxygen chemical scavenger in DMSO and DMF using Eq. 2.

\[ \Phi_{\Delta} = \Phi_{\Delta}^{\text{Std}} \frac{R . I_{\text{abs}}^{\text{Std}}}{R_{\text{Std}} . I_{\text{abs}}} \]

**Photochemical and Photochemical Parameters**

**Fluorescence quantum yield determination**

Fluorescence quantum yields (\(\Phi_F\)) were calculated by the comparative method (Eq. 1) (27, 28) using unsubstituted Zn(II) phthalocyanine as the reference. \(\Phi_F\) values of unsubstituted Zn(II) phthalocyanine are 0.20 in DMSO and is 0.17 in DMF (29, 30).
**Synthesis of Compounds**

Synthesis of (E)-3-(4-(3,4-dicyanophenoxy)-3-methoxyphenyl)acyllic acid (compound 1): Firstly, trans-4-hydroxy-3-methoxycinnamic acid (ferulic acid) (2.89 mmol, 0.5 g) was added in dry DMF (50 mL) and then 4-nitrophthalonitrile (2.89 mmol, 0.5 g) was added into the solution. The solution was mixed for 15 min to obtain a homogenous mixture. Then, anhydrous K$_2$CO$_3$ (11.56 mmol, 1.59 g) was added into the solution and the reaction volume. The system was cooled to the room temperature at 45-50 °C. The system was heated during 72 hours under nitrogen atmosphere at 45-50 °C. The solution was cooled to room temperature at the end of the reaction and diluted HCl was added to set the pH to 2. The solid particles were obtained in one hour. The particles were filtered and then washed with water, n-hexane, and diethyl ether. After drying process, light brown particles were recrystallized in MeOH. The final product was soluble in many solvents such as MeOH, EtOH, acetone, chloroform, and THF. Yield: 0.832 g (90.1%), M.p.: 225-226 °C. Anal. Calc. for C$_{18}$H$_{12}$N$_2$O$_4$ (MA: 320.30 g/mol): C, 67.50; H, 3.78; N, 8.75. Found: C, 67.30; H, 3.70; N, 8.65%. FT-IR (KBr, ν$_{max}$/cm$^{-1}$): 3073-3047 (Ar-CH), 3300-2500 (broad peak, carboxylic acid-COOH), 2981-2844 (aliphatic –CH, –CH$_2$), 2231 (C=≡N), 1688 (C=O), 1589-1487 (C=C), 1246 (Ar-O=Ar). 1H-NMR (MeOD$_3$, 500 MHz, δ ppm): 12.45 (s, 1H, -OH), 7.85-7.83 (d, 1H, Ar-H), 7.69-7.65 (d, 1H, Ar-H), 7.41-7.39 (dd, 1H, Ar-H), 7.29 (s, 1H, Ar-H-C), 7.27 (d, 1H, Ar-H), 7.21 (d, 1H, Ar-H), 7.19-7.16 (d, 1H, Ar-H). 13C-NMR (MeOD$_3$, 500 MHz, δ ppm): 170.23 (–COOH), 163.05, 153.27, 145.24, 144.50 (Ar-C≡C), 137.00, 135.57, 124.15, 123.14, 122.12, 121.75, 120.47, 118.56 (=C-COOH), 116.65 (-C≡N), 116.39 (-C≡N), 113.78, 109.76, 56.56 (O=CH$_2$). MS (LC-MS) m/z. Calculated: 320.30 Found: 359.31 (M+K$^+$).

Synthesis of (E)-3-(2,9,16,23-tetraakis-(4-oxy-3-methoxyphenyl)acyllic acid) phthalocyaninato zinc(II) (compound 2): Compound 1 was dissolved in n-pentanol (3 mL). Anhydrous Zn(CH$_3$COO)$_2$ (0.156 mmol, 0.041 g) was added into the solution and the reaction tube was heated to 80 °C under nitrogen atmosphere. Five drops of DBU were added to the solution and kept at 150-160 °C for 24 hours. While the temperature was increasing, the color of solution changed from dark brown to dark green. Then, the solution was cooled to room temperature and diluted HCl was added to arrange pH as 2-3. Green precipitates were filtered and washed with water, n-hexane, hot acetone, hot dichloromethane, hot acetonitrile, hot chloroform, hot ethyl acetate, and hot diethyl ether. The dried product was soluble in MeOH, EtOH, THF, DMSO and DMF. Yield: 0.064 g (30%). M.p. > 300 °C. Anal. Calc. for C$_{32}$H$_{49}$Zn$_3$N$_{16}$O$_{16}$ (MA: 1346.58 g/mol): C, 64.22; H, 3.59; N, 8.32. Found: C, 64.52; H, 3.45; N, 8.12%. FT-IR (KBr, ν$_{max}$/cm$^{-1}$): 465-2900 (broad peak, carboxylic acid-COOH), 3070 (Ar=CH), 2980-2870 (aliphatic-CH, -CH$_2$), 1686 (C=C), 1592-1467 (C=C), 1259 (Ar-O–Ar). 1H-NMR (500 MHz, d-DMSO) δ ppm: 12.30 (s, 4H, -OH), 8.05-7.55 (m, 12H, Ph-Ar-H), 7.29-7.16 (m, 12H, subs-Ar-H), 7.45-7.39 (m, 4H, Ar-H=Ar-C), 6.52 (m, 4H, -C=C=CH-COO), 3.35 (s, 12H, Ar-O-CH$_3$). UV–vis (DMSO, 1×10$^{-5}$ M): λ$_{max}$/nm (log ε): 682 (5.03), 614 (4.36), 349 (4.76). UV–vis (DMF, 1×10$^{-5}$ M): λ$_{max}$/nm (log ε): 680 (4.99), 611 (4.30), 352 (4.71). UV–vis (THF, 1×10$^{-5}$ M): λ$_{max}$/nm (log ε): 678 (4.98), 610 (4.30), 348 (4.70). MALDI TOF MS (m/z): Calculated: 1346.58, Found: 1346.48 [M]+, 1416.49 [M+2CI]$^+$, 1485.84 [M+4CI]$^+$.

**Photodegradation quantum yield determination**

Photodegradation quantum yield (Φ$_d$) determinations were carried out using the experimental set-up described in the literature (34–36). Photodegradation quantum yields of the sample (The synthesized phthalocyanine) were determined using Eq. 3.

$$\Phi_d = \frac{(C_0 - C_t) \cdot V \cdot N_A}{I_{abs} \cdot S \cdot t}$$

(Eq. 3)

Where $C_0$ and $C_t$ are the sample concentration before and after irradiation respectively. $V$ is the reaction volume. $N_A$ is the Avogadro’s constant. $S$ is the irradiated cell area. $t$ is the irradiation time and $I_{abs}$ is the overlap integral of the radiation source light intensity and the absorption of the sample. A light intensity of 7.05×10$^{15}$ photons s$^{-1}$.cm$^{-2}$ was employed for $\Phi_d$ determinations.

**RESULTS AND DISCUSSION**

Solutions of the photosensitizer containing DPBF were prepared in the dark and irradiated in the Q-band region using the setup described in equipment part. DPBF degradation at 417 nm was monitored. The light intensity of 2.20×10$^{16}$ photons s$^{-1}$.cm$^{-2}$ was used for $\Phi_d$ determinations.

Synthesis and Characterization of Compounds

Scheme 1 shows the general synthesis of the compounds. In the first step of synthesis, trans-4-hydroxy-3-methoxycinnamic acid and 4-nitrophthalonitrile were dissolved in DMF and anhydrous K$_2$CO$_3$ was added into the solution. The solution was heated under nitrogen atmosphere for 72 hours at 45-50 °C. Then, the solution was cooled and diluted HCl was added into the solution to obtain precipitates. The formed precipitate was washed with ultra-pure water for neutralization, the precipitate was then washed with n-hexane and diethyl ether and dried under vacuum. The structure of compound 1 was proved by elemental analysis, FT-IR, $^1$H-NMR, $^{13}$C-NMR and LC-MS techniques.

In the FT-IR spectrum of compound 1, there is no peak around 1365 cm$^{-1}$ corresponding to –NO$_2$ groups indicating the full reaction of 4-nitrophthalonitrile. Besides, obtained peaks at around 2231 cm$^{-1}$, 1688 cm$^{-1}$ and a broad peak between 2500-3300 cm$^{-1}$ on the structure of compound 1 support the (-C≡N), carbonyl (C=O) and carboxyl groups (COOH), respectively. Indeed, no peaks at around 3380 cm$^{-1}$ (–OH) supporting the reaction of trans-4-hydroxy-3-methoxycinnamic acid to form of compound 1. Aliphatic -CH and -CH$_3$ peaks at around 2981-2844 cm$^{-1}$ and Ar-O-Ar etheric peak at 1246 cm$^{-1}$ support the formation of compound 1.

$^1$H-NMR analysis of compound 1 also proves the formation of expected structure of this compound. Chemical shifts at around 7.85–7.83, 7.69–7.65 and 7.41–7.39 ppm correspond to aromatic protons to which the nitrile groups are attached. Other aromatic protons were determined in 7.27, 7.21 and 7.19–7.18 ppm as total of three protons. The chemical shifts at around 7.29, 6.83–6.50 and 3.78 ppm were related with Ar-CH=C for one proton bonded aromatic ring, C=CH-COO for one proton and –OCH$_3$ for three protons, respectively. The signal at 12.45 ppm was related with –OH group (22).

$^1$H-NMR spectrum supports the formation of compound 1 with total of 12 protons. $^{13}$C-NMR analysis of compound 1 also supports the formation of proposed structure of this compound. The carbon peaks bonded with nitrite groups were determined at 116.65 and 116.39 ppm. The –OCH$_3$ bonded carbon peak was also observed at around of 56.56 ppm. $^{13}$C-NMR spectrum also demonstrates the formation of compound 1 with total of 18 peaks for the carbon atom.

The observed peak at 359.31 [M+K]$^+$ in the mass spectrum also confirms structure of compound 1. Finally, the results of experimental elemental analysis data are consistent with the theoretical data of compound 1 and are satisfactory for the formation of this compound.

Compound 2 was synthesized by cyclotetramerization of compound 1 in presence of Zn(OAc)$_2$ and DBU in dry n-pentanol at 150-160 °C (Scheme 1). Upon addition of diluted HCl to solution of the mixture until pH 2–3, carboxylic acid group bearing compound 2 were obtained. The obtained product was washed many times different solvents and was dried under vacuum. In the synthesis of tetra-substituted zinc(II) phthalocyanine, a mixture of four possible structural isomers occurs. These isomers can be explained by their molecular symmetry as C$_{16}$, C$_{2y}$, C$_{4n}$ and D$_{2v}$. Herein, the synthesized compound 2 is formed as isomer mixtures as expected. No attempt was made for separating the isomers of compound 2. The structure of compound 2 was verified by FT-IR, elemental analysis, UV-Vis, $^1$H-NMR, and MALDI-TOF MS techniques. The results are consistent with the expected structure.

In the FT-IR spectrum of compound 2, the any peak was observed at around 2231 cm$^{-1}$ supported formation of compound 2 by cyclotetramerization reaction. Besides, the peaks at around 1686 cm$^{-1}$ and 2500-3300 cm$^{-1}$ on the structure of compound 2 belong to the carboxyl group (–C=O) and carboxylic acid group, respectively. The peaks at 1259 cm$^{-1}$ and 2930-2870 cm$^{-1}$ are related with Ar-O-Ar ether and aliphatic –CH and –CH$_3$ supporting the formation of compound 2.

The $^1$H NMR spectrum of compound 2 exhibits quite broad signals when compared with that of starting compound 1 derivative. The OH protons were observed with a total of 4 protons at 12.30 ppm. The pC ring protons were detected between 8.05 and 7.55 ppm integrating for a total of 12 protons. Aromatic functional group protons were observed with a total of 12 protons at 7.16 ppm. The protons with a total number of 8 at 7.45–7.39 and 6.52 ppm are related with Ar-CH=C and –C=CH-COO groups, respectively. Finally, the protons with a total number of 12 were observed at around 3.35 ppm as singlet for the –O-CH$_3$ groups.

UV-Vis spectrophotometry plays an important role to clarify the structure of metallo-Pcs. Pcs are colored substances and give specific absorption peaks in the visible and ultraviolet regions. Pcs show typical UV-Vis spectra with two characteristic absorption bands, one in the UV region at about 300-400 nm is the B band and the other one in the visible region at 600-700 nm is the Q band, both are based on π-π* transitions (37). The Q band is also a characteristic peak for differentiating metallo and metal-free Pcs. While the metal-free Pcs give two equal bands at 600-700 nm, the metallo Pcs give a single band. UV-Vis spectra of compound 2 were recorded in THF, DMF, and DMSO solvents and can be seen in Figure 1. These spectra show monomeric behavior evidenced by a single (narrow) Q band (at around 678–682 nm) in THF, DMF, and DMSO. The Q band and its shoulder of compound 2 were
determined as a single band at 682 and 614 nm in DMSO, 680 and 611 in DMF, and 678 and 609 nm in THF, respectively and B band of compound 2 was also observed at 349 nm in DMSO, 352 nm in DMF, and 348 in THF, respectively supported the formation of compound 2. The obtained compound 2 exhibits a single Q band, indicating that it contains the metal ion in the macrocyclic cavity.

Scheme 1: General synthesis procedure of compounds 1 and 2.
The obtained [M]$^+$ m/z:1346.48, [M+2Cl]$^+$ m/z:1416.49, [M+4Cl]$^+$ m/z:1485.84 peaks in MALDI TOF MS spectrum also support the formation of compound 2 (Figure 2). Finally, the results of experimental elemental analysis data are consistent with the theoretical data of compound 2 and are satisfactory for the formation of this compound.

**Aggregation properties of compound 2**

The aggregation properties of PCs have been known since the discovery of these substances (38, 39). Generally, aggregation is a common association of molecules in solution, which is the overlaying of two or more macro-ring structures due to intermolecular attraction forces. A co-planar relation of macrocyclic rings and progresses through the assembly of monomers to dimers and higher-order aggregates are effective on aggregation behavior. With aggregation, the structure of compound can change from

---

**Figure 1:** UV-vis spectra of compound 2 in different solvents.

**Figure 2:** MALDI-TOF MS spectrum of compound 2.
monomer to dimeric, trimeric, or oligomeric structure. The structure of the PCs (neutral, metal, cationic, etc.), size, position of the substituent group, substituents in the peripheral position, solvent and temperature are very effective on aggregation. In the case of PCs aggregation, the interactions between the electronic molecules change the physical and chemical properties. Aggregation is the most important factor affecting the photochemical and photophysical behavior of PCs. The resolution of PCs is reduced due to aggregation and this is an unwanted situation in applications such as PDT (40, 41). In particular, in water and other polar solvents, the macrocyclic Pc becomes an aggregate due to its hydrophobic nature. For this reason, DMSO and DMF solvents which are dipolar aprotic solvents, have similar physical properties and which do not cause aggregation have been chosen. Water, DMSO and DMF are used in many similar applications. Aggregation not only leads to a decrease in solubility, but also decreases the quantum efficiency of fluorescence and singlet oxygen. This means that the sensitivity to light for Pc is reduced (42). To reduce these limiting factors and maintain effective photoactivity, Pc may be substituted with various ligands, such as carboxylic acid groups at the peripherally position (24). In this study, the purpose of the aggregation assay is to examine whether compound 2 conforms to the Lambert-Beer law in DMSO and DMF solvents at specific concentrations and to determine if they have undergone aggregation. To make these measurements, the solutions of compound 2 in DMSO and DMF were separately prepared. The UV–vis spectra for compound 2 were examined in both DMSO and DMF under different concentrations ranging from 12x10^{-6} M to 2x10^{-6} M. UV-Vis spectra in Figures 3 and 4 show the aggregation behavior of compound 2 in DMSO and DMF, respectively. At the end of this investigation, it was found that the compound 2 conformed to the Lambert-Beer law and there was no aggregation in DMF and DMSO. When Figures 3 and 4 are examined, it is seen that due to the increase in concentration, the Q-band rises but there are no new bands (normally blue-shifted) due to aggregation. The linear variation in the absorbance of the Q band with increasing concentration confirms that there is no tendency to aggregation.

Figure 3: Aggregation behavior of compound 2 in DMSO at different concentrations (Inset: Absorbances versus concentrations).
Figure 4: Aggregation behavior of compound 2 in DMF at different concentrations (Inset: Absorbances versus concentrations).

Photophysical properties of compound 2
The fluorescence excitation, emission, and absorption spectra of compound 2 in DMSO and DMF are depicted in Figures 5 and 6, respectively. Table 1 also shows fluorescence emission, excitation, absorption peaks and stokes shift values of compound 2. Stokes shift values have been found in the observed region. The observed stokes shifts for compound 2 are 12 in DMSO and are 10 in DMF. The obtained stokes shifts of the compound have been found to be compatible with unsubstituted zinc(II) phthalocyanine (43). The compound exhibits similar fluorescence behavior in both solvents, excitation and absorption spectra are similar and they appear to be mirror images in both solvents. The wavelengths of the Q band of absorption and the Q band of excitation is proximity and this situation assumes that the nuclear configurations of the ground and excited states are similar and they are not affected by excitation (44). One of the important problems affecting fluorescent behavior of Pcs is aggregation. The reason for this is that the compounds of agglomerated phthalocyanine do not have fluorescence in the solution medium. Compound 2 obtained in this work did not exhibit any aggregation in DMSO and DMF. For this reason, the compound 2 exhibits fluorescence behavior in both solvents.

The photophysical properties such as fluorescence quantum yield of photosensitizers are highly significant parameters in PDT applications because of the imaging necessity of the photosensitizer in the human body. The fluorescence quantum yields ($\Phi_f$) for compound 2 in both DMSO and DMF are given in Table 2. The $\Phi_f$ values for compound 2 in both solvents are compatible with typical zinc(II) Pcs (29) and are found similar with $\Phi_f$ values of unsubstituted standard zinc(II) phthalocyanine in DMSO and DMF (29). These values reveal that the substitution groups of compound 2 are not have important effect on the fluorescence behavior. But the solvent may have little effect (45). Therefore, the compound 2 has showed slightly higher $\Phi_f$ values in DMSO (0.23) compared to DMF (0.17).

**Photochemical properties of compound 2**

The photochemical properties include values such as singlet oxygen quantum yields and photodegradation quantum yields. Pcs act as photosensitizers in PDT of some cancers. The photosensitizer, which is activated by a certain light, is excited and molecular oxygen is converted into a reactive oxygen species such as singlet oxygen. This singlet oxygen helps to destroy the cancerous cells. Because singlet oxygen is highly reactive, it can normally damage healthy cells. But it is unstable, it exists very briefly and its effective area is short. Therefore, healthy cells can be minimally damaged (12). The calculation of the singlet oxygen quantum yield is important in PDT. In this study, for singlet oxygen quantum yield measurements; the solutions of compound 2 in both DMSO and DMF at $1 \times 10^{-5}$ M concentration were prepared and then 1,3-difenilisobenzofuran (DPBF) (quencher) which prepared at $3 \times 10^{-5}$ concentration was added into these solutions. The mixtures were exposed to light of $2.20 \times 10^{16}$ photon/(s.cm$^2$) intensity at a certain time and UV-Vis spectra of these mixture were separately taken. The change in absorption at 417 nm of the DPBF compound was investigated and singlet oxygen quantum yields were calculated using Eq. 2. The same procedure was made for std-ZnPc in DMSO and DMF for comparative purposes. Figures 7 and 8 show the UV-Vis spectral changes during the measurement of singlet oxygen quantum yield of the compound 2 in DMSO and DMF. The figures show that the concentration of DPBF decreases over time with light irradiation. The Q band intensity of compound 2 does not show a significant change as a result of exposure to light, indicating that the compound is not degraded during single oxygen measurements (Figures 7 and 8). The calculated data are given in Table 2. The results show that the calculated $\Phi_\Delta$ values in DMSO and DMF are slightly lower than the std-ZnPc (29). Substituted groups in the peripheral locations may cause in a slightly lower $\Phi_\Delta$ value. It is known in the literature that Pcs containing substituted groups in peripheral positions reduce singlet oxygen generation (46). Although compound 2 has slightly low $\Phi_\Delta$, it has enough singlet oxygen generation as photosensitizers for PDT application area. The obtained values of singlet oxygen quantum yields for compound 2 in DMSO and DMF are typical for metal Pcs (47, 48).
When Pcs are exposed to light irradiation during measurement, they may be degraded. This process is an important parameter for the use of Pcs as photosensitizers. Photodegradation quantum yield ($\Phi_d$) is durability of a molecule against light. $\Phi_d$ can be calculated by examining the change in the absorption spectrum of compound during the light irradiation. Photodegradation in Pcs is observed with a decrease in the Q band. The photodegradation
quantum yields are calculated through Eq. 3 using the slopes of the calibration graphs generated at specific time intervals. In this study, the sensitivity of the compound to light was measured. For these measurements, firstly, the solutions of the compound 2 in both DMSO and DMF solvents were separately prepared and then the mixtures were exposed to light of 7.05x10^{15} photon.s^{-1}.cm^{-2} intensity at a certain time and UV-Vis spectra of these mixtures were separately taken and the change in the Q band of compound 2 was investigated. Figure 9 for DMSO solution and Figure 10 for DMF solution show absorbance change during photodegradation quantum yield measurements of compound 2 showing the decreasing of the Q and B bands. As it can be seen from figures, there are no significant decrease in Q band of compound 2 in both solvents. The \( \Phi_d \) values of compound 2 in DMSO and DMF were found the order of 10^{-5} (Table 2). Ordinary values for stable Pcs are of the order of 10^{-6}, but these values for unstable Pcs are of the order of 10^{-3} (49). The \( \Phi_d \) value of compound 2 is 1.08x10^{-5} in DMSO and is 4.44x10^{-5} in DMF. These values are typical for zinc Pcs bearing different substituents on the peripherally as described in the literature (50, 52). The \( \Phi_d \) value in DMSO is slightly lower than unsubstituted zinc(II) phthalocyanine (\( \Phi_d:2.61x10^{-5} \)). But the \( \Phi_d \) value in DMF is slightly higher than unsubstituted zinc(II) phthalocyanine (\( \Phi_d:2.30x10^{-5} \)). According to the data obtained, compound 2 in DMSO is slightly stable than compound 2 in DMF due to having lower \( \Phi_d \) value.

**Figure 9:** Absorbance changes during the photodegradation study of compound 2 in DMSO (Inset: plot of Q band absorbance versus time).
CONCLUSION

In summary, this study reports synthesis, characterization and photochemical and photophysical properties of ferulic acid substituted zinc(II) phthalocyanine for the first time. The synthesized phthalocyanine has solubility in many solvents such as THF, DMSO and DMF and it does not exhibit any aggregation in the mentioned solvents. Fluorescence quantum yield, singlet oxygen quantum yield and photodegradation quantum yield of this phthalocyanine were also determined in DMSO and DMF solvent to reveal their potential in PDT applications. This phthalocyanine gives good results as photosensitizers for PDT treatment.
