Abstract: In this work, a novel S-substituted bioactive anthraquinone compound is synthesized with a new, easy and less energetic reaction method from 1-chloro-9,10-dihydrodioxyanthraquinone and butyl-3-mercaptopropionate (Compound 3) for the first time in the literature. The synthesized structure is purified by column chromatography and then characterized with various spectroscopic methods (NMR, MS, FT-IR, UV). The investigation of the antimicrobial properties of the purified structure reveals remarkable biological properties. Compound 3 is not only effective against yeasts and fungi but also displays significant inhibitory effects on the growth of the tested Gram positive bacteria similar to that of a positive control (Gentamicin). Subsequently, biodegradable electrospun mats are produced via electrospinning method for their usage as a biomaterial. Structural (FTIR), morphological (FEG-SEM) biological (antimicrobial and in-vitro tests) and mechanical (tensile testing) characterizations are conducted for these nanobiomaterials. Presenting an advantage of the novel antimicrobial compound, all produced electrospun nanocomposites exhibit remarkable cell viability% and mechanical properties as the amount of Compound 3 increases. Cell viability values are 95% or greater for all polymeric nanocomposites whereas, the best cell viability% and mechanical properties are obtained for PCL-8% Compound3 composite. The obtained electrospun mats are good candidates for biomaterials for tissue engineering purposes and wound healing materials with a purposeful compound synthesis and a subsequent nanobiocomposite production.

Keywords: Anthraquinone, synthesis, biodegradable material, electrospun mat, biomaterial.

INTRODUCTION

Natural products have great potential for medical applications. Recently, anthraquinone derivatives have gained special interest owing to their large potential applications as antifungal, antiviral, antibacterial agents for biological activities (2-6). Aloe-emodin, an anthraquinone derivative, is a potential antileukemic material (7). This molecule chemically stimulates the growth and proliferation of normal mouse splenocytes and shows dose-dependent cytotoxicity against cancer cell lines. On the other hand, being effective to various cancer type and multiple sclerosis, Mitoxantrone, an anthraquinone analogue, is known as a synthetic anticancer analog of anthracycline antibiotics (8-12). Several studies have been conducted to understand the mechanism of mitoxantrone and it is revealed that the nuclear DNA is the primary target and the planar anthraquinone ring inserts between DNA base pairs. Consequently, negatively charged phosphate groups of DNA are found to bind to the nitrogen-containing side chains (13-15). Being an anticancer drug, Mitoxantrone is
a valuable inhibitor for the enzymes that are responsible for repairing a damaged DNA (16,17). Several anthraquinone analogues have been evaluated as potential materials in various applications.

Recently, many studies have been conducted with both isolated [18,19] and synthesized anthraquinone derivatives [20,21] since they present potential therapeutic uses such as antibacterial, antifungal agents, and in other biological activities. Furthermore, various functional groups have been substituted to anthraquinone molecules to improve biocompatibility, antimicrobial and anticancer properties for tissue engineering purposes. Among these molecules, amino, hydroxy, metoxy, cyano, thiazoline, and thiophene etc. derivatives [22-25] have been synthesized. Although, for naphthaquinones, a family of quinones, thiol derivatives have been evaluated detailly for their antibacterial and antifungal activity [26], very few studies have been conducted with thio-substituted anthraquinones to identify their biological properties [27]. Moreover, in the literature some isolated natural thioanthraquinone derivatives were extensively used for their antimicrobial and anticancer properties [28]. These investigations have been the motivation of this work to focus on the synthesis of anthraquinone molecules and their subsequent nanocomposite production for tissue engineering materials.

Synthesis of some anthraquinone derivatives in the literature have been conducted with expensive and hardly obtained chemicals like cesium carbonate. Also organic solvents, which are hazardous and hardly purified, are used for such synthesis under nitrogen conditions (29,30). Thus sustainable production of an anthraquinone has become difficult. In our previous study, a novel practical, economical and one-step synthesis methodology has been established to simple synthesis of anthraquinone derivatives (1). Ethylene glycol is used as an organic solvent in the present study. Since reactions are conducted under heat, the usage of nonvolatile, readily available and inexpensive solvent such as ethylene glycol presents the novelty of our synthesis method. On the other hand, being biocompatible, biodegradable and presenting higher mechanical properties in comparison to its natural polymer analogues, Polycaprolactone (PCL) is preferred especially in tissue engineering applications. Moreover, the degradation products (succinic acid, butyric acid, valeric acid and caproic acid) of PCL don’t present a toxic effect and inflammatory reactions. These effects make PCL preferable in the regeneration of bone, epidermis, nerve and retina in tissue engineering (31,32). The synthetic polymer PCL, among the few FDA (Food and Drug Administration) approved polymers and present antimicrobial effect can be utilized as biomaterials for such purposes (33).

Electrospinning is an efficient technique that is used for the fabrication of polymer nanofibers. In recent years, various polymeric and composite solutions have been successfully converted into electrospun mats of ultrafine fibers (34,35). Presenting higher volume/surface area, these nanofiber mats result in superior properties especially in biological (antimicrobial and cell adhesion) and mechanical aspects (31, 36, 37). As a consequence of these, obtained electrospun mats can have potential applications as regenerative or wound healing biomaterials in tissue engineering (38,39).

In the present paper, a comprehensive study has been conducted starting from the synthesis of a novel, biologically active compound, and its production of to electrospun biocomposites. The obtained biomaterials can find applications as wound healing material or a biomaterial for regenerative tissue engineering purposes.

MATERIALS AND METHODS

Materials and Characterization
All chemicals are obtained from Sigma Aldrich and used as received. The obtained products are purified by column chromatography on Silica gel (Fluka Silicagel 60, particle size 63-200 µm). TLC plates coated with silica 60F254 (Merck, Darmstadt) are used under ultraviolet light (254 nm). To identify the melting points of the products, a Buchi B-540 melting point apparatus is used. Structure investigations for both Compound 3 and the nanocomposites are identified by Fourier transform infrared (FTIR) spectroscopy. The IR spectra were recorded on a JASCO (model 6600) FTIR spectroscopy in the region 400–4000 cm⁻¹ at a resolution of 1 cm⁻¹ and 8 scans are performed for each detection. ATR technique is used. UV spectrum is gauged by using Shimadzu UV-VIS Spectrophotometer 2600. ¹H and ¹³C NMR spectra are conducted by Varian UNITY INOVA which are operated at 500 MHz. Mass analysis is done on a Thermo Advantage MAX LC/MS/MS spectrometer.

Synthesis and structural characterization of thio-substituted anthraquinone (Compound 3) (1)
1-Butylpropionylthio-9,10-dioxo-anthraquinone (3)
Cl substitution on anthraquinone ring can give a nucleophilic substitution reaction and different nucleophilic groups can chemically bond to the ring. Compound 3 is synthesized from the reaction of 1-chloro-9,10-dioxo-anthraquinone 1 (1 g, 4.12 mmol) with butyl-3-mercaptopropionate 2 (0.66 g, 4.06 mmol) in a mixture of ethylene glycol and aqueous KOH solution (1). Orange solid, mp: 153-154 °C. Yield: 1.18 g (78%)
Photericin B (Sigma 1032007) is used for identification of the qualitative antibacterial act.

In order to specify the quantitative antibacterial effect, Mueller–Hinton broth (Fluka 70191) is utilized for identification of the qualitative antibacterial effect and to provide the strains. In order to specify the quantitative antibacterial effect, Mueller–Hinton broth (Fluka 70191) with MgCl₂·2H₂O (10 mg Mg²⁺/L) and CaCl₂·6H₂O (20 mg Ca²⁺/L) are used as a medium. Furthermore, gentamicin sulfate (Sigma G1272) is used as the reference antibiotic standard. 10 serial dilutions of the thio-anthraquinone compound between 0,01 mg/mL – 5,4 mg/mL with CAMBH are prepared in sterile tubes. 1 ml of each inoculum is poured to each petri dishes and 9 ml of Muller-Hinton agar which is brought to 50 °C and is added onto inoculum. Subsequently, it is mixed with a circular dial until cooling to room temperature. Bacterial suspensions with 10⁷ cfu/ml final concentration are prepared and added into the microplate wells. The sterilized replicator with 3-mm pins which deliver 2 μL are placed into the microplate to soak the pins and transferred onto the agar plate. The agars are incubated at 37 °C for 24 hours. The minimum inhibitory concentration, MIC, value is determined beyond the level no inhibition of growth of test organisms are observed.

b) Antifungal activity of thio-anthraquinone (Compound 3). The antifungal effect of the thio-anthraquinone compound against yeast and fungi is examined with minimum inhibitor concentration using (MIC) broth macro dilution method according to CLSI (32). The antifungal activities are evaluated against yeasts (Candida albicans, Malassezia pachydermatis) and fungi (Microsporum canis and Trichophyton mentagrophytes).

Suspension equal to 0.5 McFarland turbidity in physiological saltry water among 48-hour C. albicans and M. pachydermatis strains and 5 days M. canis and T. mentagrophytes strains in Sabouraud Dextrose Agar (SDA) (Sigma S3181) are prepared in order to get the inoculum. The MIC of the compound is determined by two-fold micro-dilution method in RPMI 1640 Medium (Sigma R8758) according to CLSI. Amphotericin B (Sigma 1032007) is used as the positive control. The lowest concentration that completely inhibits the reproduction and can be determined with the naked eye, i recorded as the MIC value.

**Preparation of electrospinning solutions**

Polyacrylactone, average molecular weight (Mw) 80,000 g/mol, is obtained from Sigma-Aldrich and used without further treatment or purification. PCL is dissolved in chloroform/dimethylformamide (DMF) solution with a constant w/w 3:2 ratio. On the other hand, the synthesized ester-substituted thio-anthraquinone compound is also added to the obtained solution and both of them are stirred sufficiently at range of 30-40 °C. Different compositions are prepared as 6% PCL, 6% PCL-1% Compound 3, 6% PCL-5% Compound 3 and 6% PCL-8% Compound 3.

Properties of the electrospinning solution (viscosity, molecular weight of the polymer),
should be determined before the jet. High molecular weight PCL is chosen purposefully in the present study, in order to produce nanofibers not nanoparticles. If lower molecular weight ones are used, low viscous solutions are obtained and hence the presence of beads are observed. Whereas, with very high molecular weight polymer, fibers wider than nano scale are produced which is not preferred. The viscosity of polymeric solution has been adjusted as well, to maintain nanofibers and optimize their fiber sizes, hence their morphology. Too high a viscosity results in drying of the droplet when coming out at the tip of the needle. PCL solution density is adjusted as 6% PCL and so the viscosity. So as an optimum solution viscosity and Mw is chosen for continuous smooth fibers without any agglomeration and beads.

**Production of Nanobiocomposite Mats via Electrospinning Method**

In order to get nanofiber structures but not nanoparticles solution parameters should be determined and process parameters should be adjusted. (a) The prepared electrospinning solution (b) Nanocomposite mat production via electrospinning method (Figure 2.).

![Image](image1.png)

**Figure 2. (a) The electrospinning solution (b) Nanocomposite mat production via electrospinning method.**

One of the most important parameters among the controllable variables during electrospinning is the applied voltage. Taylor cone is an indication of the critical voltage for electrospinning to occur. The critical voltage depends on the distance between the collector and the tip, surface tension of the solution, the tip radius and length of the pipette. Once the critical voltage is reached, the electrical force become sufficient to overcome the surface tension resulting in a taylor cone for electrospinning. Higher voltage yields to better electrospun fibers in nanoscale. Size of the fibers can also be easily varied by altering the distance between the tip and the collector. When the distance between the tip and collector are too small, the fibers are deposited on the collector even before the solvent evaporates. Schematic representation of the electrospinning method (Figure 3.).

To obtain homogenous fiber structures, process parameters have been set. The applied voltage is in the range of 15-31.8 kV while a Taylor cone is observed at a voltage of 12.3 kV. Humidity of the internal process area is recorded as 44.6±5%. The flow rate of the digital syringe pump is 1 ml/h and the average distance between the tip of needle and collector is set to 12 cm. Solution parameters of the obtained biocomposite electrospun mats are given in Table 1.

In the present study, solution parameters are also determined. Table 1 summarizes the solution parameters that are worked with. Increasing the crystalline content by incorporating Compound 3, mixture temperature or the mixing time to maintain a clearly dissolved solution increased (42,43). This can be attributed to the rigid anthraquinone structure which increases the crystallinity (37,44).

Characterization of the Nanobiocomposite Mats
Morphological investigation of PCL and PCL composites having 1%, 5%, 8% Compound 3 by electrospinning method have been performed using FEI Quanta 450 FEG model scanning electron microscope (FEGSEM) under an applied voltage of 7.0 kV. Dimensional analysis and the topological investigation have also been conducted for the samples. Nanofibers’ diameters are estimated using Image J software (National Institutes of Health, Bethesda, MD, USA) over 100 places in SEM images. Additionally, topologies of the samples are calculated similarly (45,46).

Tensile tests of the electrospun nanofiber mats (PCL and PCL composites having 1%/5%/8% content of Compound 3) are conducted according to ASTM E4 standards. Tensile strengths of the nanofiber mats are calculated before the mechanical test and are in the range of 0.01-0.18 mm. Tests have been carried out at a constant jerk of 5 mm/min at a jaw distance of 10 cm (32). Elongation values and UTS (ultimate tensile strength) points are measured by Instron 4411 tensile test machine with specific software (Bluehill 2, Elancourt, France). Each set of sample is tested 5 times and their averages are taken.

For antibacterial effect detection of the electrospun mats, the agar dilution method according to clinical and laboratory standards institute (formerly CLSI) is performed quantitatively (3,47). The antimicrobial activities are assessed against Gram-positive (Staphylococcus aureus (ATCC 29213)), and Gram-negative (Escherichia coli (ATCC 25922)) bacteria and yeast (Candida albicans).

In-vitro tests for the electrospun mats have been conducted as follows;

Sample Preparation:
The nanocomposite mat films are cut to 10 x 10 mm and the films are washed 3 times in 70% ethanol. In the third wash, the samples are left in the alcohol for 30 min. The samples are then washed 3 times with PBS for 5 minutes. One sample from each group is covered with culture media and kept in incubator at 37°C for 48 hours for degradation and contamination control.

Cell culture:
After control experiments, samples are cultured with immortalized human lung bronchial epithelial cell line (BEAS-2B) to detect any toxic effects of the molecule. 6x10^6 cells are seeded on three samples from each group with 200 µl culture media (RPMI 1640 with 10% Fetal Bovine Serum and 1% Penicillin/Streptomisin). After 10 minutes, 1.8 ml of culture media is added to each well of culture plates. Three wells without polymers are used as controls. The samples are then incubated with the cells for 72 hours and observed on an inverted microscope after 24, 48 and 72 hours, they were observed on an inverted microscope. After 72 hours, the cells are microscopically examined for viability. The wells are collected, washed with PBS and fixed with 70% methanol for 20 minutes in a refrigerator. For the detection of dead cells, samples are stained and incubated with 100 ng/ml propidium iodide (PI) solution for 10 minutes. The cells are evaluated and photographed under a Zeiss AxioScope Z1 LED fluorescent microscope (48-51).
RESULTS AND DISCUSSION

Synthesis and characterization of ester-substituted thio-anthraquinone compound
The synthesized of thio-anthraquinone compound has been obtained by the reaction of 1-chloro-9,10-dihydroxy-anthraquinone (1) and butyl-3-mercaptopropionate in a mixture of ethylene glycol and aqueous solution of KOH (1). The obtained thio-anthraquinone compound is an orange solid and is stable. The resultant thio-anthraquinone compound has been synthesized for the first time in the literature and its applications as a biomaterial are discussed in the present study.

Structural characterization results of ester-substituted thio-anthraquinone compound
The characteristic –C=O band of anthraquinone skeleton for Compound 3 is detected at 1671 cm\(^{-1}\); on the other hand, 3019 cm\(^{-1}\) and 1557 cm\(^{-1}\) can be attributed to the aromatic structure in the IR spectrum. In the \(^{13}\)C NMR of compound 3, carbon atom of the ester carbonyl gave a peak at 184.25 ppm whereas, in \(^{1}\)H NMR characteristic sulfur-hydrogen peaks are detected at 2.59 and 3.17 ppm. Moreover, the molecular ion peak of S- substituted anthraquinone compound 3 is observed at m/z 369.65 [M+H]+.

Antimicrobial Test Results of ester-substituted thio-anthraquinone compound
It is found that the thio-anthraquinone compound demonstrates effectiveness against \(S.aureus\), \(S.epidermidis\) and \(B.subtilis\) (0,27 mg/mL). It is observed that the extract has no activity on \(Enterococcus faecalis\), \(Escherichia coli\), \(Klebsiella pneumoniae\), \(Pseudomonas aeruginosa\), and \(Salmonella enteritidis\). Regarding the antibacterial activity, the results reveal that the compound displays significant inhibitory effects on the growth of the tested Gram positive bacteria similar to that of a positive control (Gentamisin). No antibacterial activity has been observed against all of the tested Gram negative bacteria. The result concerning the in vitro antibacterial activity of the thio-anthraquinone compound is presented in Table 2.

Table 2. The result concerning the in vitro antibacterial activity of the Thio-anthraquinone compound.

The effectiveness of the thio-anthraquinone compound is recorded effectiveness in different concentrations against yeasts and fungi. The compound showed a significant activity against \(C.albicans\) (0,0675 mg/mL) and \(M.pachydermatis\) (0,0843 mg/mL) and moderate inhibitory activity profile against \(M.canis\) and \(T.mentagrophytes\) (0,27 mg/mL). The results concerning the in vitro antifungal activity of the compound with MIC values are presented in Table 3. Regarding the antibacterial and antifungal activity, the results reveal that the thio-anthraquinone compound displays significant inhibitory effects on the growth of the tested Gram positive bacteria as \(S.aureus\), \(S.epidermidis\), \(B.subtilis\) and yeasts as \(C.albicans\), \(M.pachydermatis\). Additionally, antifungal activity against fungi is moderate and any antibacterial activity is not determined against all of the tested Gram negative bacteria.

Production and Characterization of Nanobiocomposites
PCL and ester-substituted thio-anthraquinone (Compound 3) solution was successfully converted into solid nanofibers through a single fluid-blending electrospinning. Calculated amounts of PCL and Compound 3 were used to obtain nanofiber mats. The nanofibers were produced with a single cone during electrospinning and exhibit homogenous morphology and without any agglomeration or discerned bead of Compound 3. For all nanfiber composites FEGSEM images with two different magnifications (3000x and 12000x) as well as their topology and fiber diameter histograms are illustrated in Figure 5. Illustrated.
Structural Characterization Result

FTIR Spectra of thio-anthraquinone (Compound 3) and PCL-8% Compound 3 Nanocomposite are shown in Figure 4. For the nanocomposite, aliphatic -CH₂ stretching can be observed in between 2945-2866 cm⁻¹. The bands at 1164 cm⁻¹, 1239 cm⁻¹ and 1294 cm⁻¹ are due to the symmetric stretching of C-O-C groups in the polymer. The strong band at 1721 cm⁻¹ belongs to the characteristic carbonyl (C=O) stretching for PCL (52) Moreover, aromatic bands at 3019 cm⁻¹, aliphatic stretching bands between 2800-2900 cm⁻¹ and bands between 1200-1000 cm⁻¹ comes from the synthesized thio-anthraquinone structure. The distinguishable bands for thio-anthraquinone Compound 3 on the other hand, carbonyl (C=O) and aromatic (C=C) peaks, are observed at 1676 cm⁻¹ and 1573 cm⁻¹ respectively (53).

FEGSEM images of nanocomposites at two different magnifications (3000x and 12000x), their histograms and topological views are shown in Figure 5. PCL and ester-substituted thio-anthraquinone (Compound 3) solution is successfully converted into solid nanofibers through a single fluid-blending electrospinning. Calculated amounts of PCL (as indicated in materials and methods section) and Compound 3 were used to obtain nanofiber mats. The nanofibers were produced by a single cone electrospinning method and homogenous morphology, without any agglomeration or discerned bead of Compound 3, are obtained. For all nanofibers, FEGSEM images with two different magnifications (3000x and 12000x) as well as their topology and histogram of the fiber diameters were illustrated. In all the nanofiber mats, the size distribution is narrow and the histograms reveal that the size of the produced nanofibers are in the range of nanoscale. By incorporation of Compound 3, the solution conductivity is increased due to anthraquinone structure, hence thinner and finer fiber formation is achieved (42,54). As a result, when FEGSEM images and histograms of the biocomposite mats are examined, a noticeable decrement in mean fiber diameters is observed.
Morphological Characterization and EDS Test Results

A. FEGSEM images for PCL nano mats at two different magnifications (3000x and 12000x), histogram and topology of PCL nano mats.

B. FEGSEM images for PCL-1% Compound 3 SEM nano mat at two different magnifications (3000x and 12000x), histogram and topology of PCL-1% Compound 3 nano mats

C. FEGSEM images for PCL-5% Compound 3 SEM nano mat at two different magnifications
Additionally, topology investigations reveal that porosity of the nanofiber mats are decreased owing to thinner fibers, thus enabling more uniform coatings and diameters distribution of the fibers. The porosity is important in cell growth and regeneration. For such a porous biodegradable biomaterial cells can find (42, 55-57).

**Antimicrobial Test Results**

Figure 6 shows the antimicrobial test results of the nanocomposites. as it is seen in Figure 7, the best antimicrobial activity can be seen for PCL/5% Compound 3 samples. PCL/Compound 3 composite nanofibers have different antimicrobial effect against Gram (+) positive and Gram (-) negative bacteria and yeast. Considering the results, PCL/Compound 3 composite nanofibers are highly active against proliferation of the *Candida albicans* fungal colonies, moderately effective against Gram (+) positive *Staphylococcus aureus* strains and not very effective against *Escherichia coli* which is Gram (-) negative bacteria strain.
Figure 6. Antimicrobial results of the samples against three different kinds of microorganisms.

In comparison to PCL/5% Compound3 nanocomposite, PCL/8% Compound3 nanocomposite is less effective against all microorganisms. This can be attributed to the agglomeration of Compound 3 and bead accumulation on nanofibers as can be supported by SEM images of PCL/8% Compound3 composite system. Irregularities such as bead formation or agglomeration on nanofiber mat ensure the adhesion of bacteria to the surface of the material. These homogeneities in the structure adversely affect the antimicrobial properties of the material (42, 58, 59).

It was determined that there is no suitable environment for the adhesion and repletion of bacteria on flat surfaces. Such a flat surface hinders adhesion to the surface material (60, 61). For this purpose, to increase the antimicrobial activity of this active compound, nanofiber production are planned and conducted during this study (62-64). In comparison to PCL the electrospun nanomat of PCL presents a slightly enhanced antimicrobial activity (65,66). As it can be seen from the FEGSEM images, nanobiocomposites are found to be homogeneous and thinner nanofibers are produced as stable anthraquinone as percentage increases. This result is due to the conductivity increase of the solution by incorporation of Compound 3 and enhanced antimicrobial effect of our novel thio-anthraquinone compound.

CONCLUSIONS

A novel and simple synthesis method for biologically active ester-substituted anthraquinone derivative has been reported by our previous study. Having antimicrobial and bioactive properties, this stable thio-anthraquinone derivative can find applications in drug delivery systems or in biomedical studies for regenerative and healing purposes.

Using this biologically active ester-substituted anthraquinone derivative nanocomposite mats have been produced. Nanocomposite morphologies have such a porous structure that can permit cell migration and growth. For the produced nanofiber mats cell viability percentages are found over 95% and enhanced mechanical properties are obtained by Compound 3 incorporation. The results indicate that the purposefully produced electrospun nanofiber composites from this novel antimicrobial, biocompatible, ester-substituted anthraquinone compound hold potential for functional tissues, biomaterials such as stents and catheters or as wound healing materials.
