Effects of cholinergic compounds and TNF-alpha on human erythroleukemia K562 cell proliferation and caspase expression

Kolinerjik bileşiklerin ve TNF-alfanın insan eritrolösemi K562 hücre köşge kalmasına ve kaspaz ekspresyonuna üzerine etkileri

Zehra KANLI, Banu AYDIN, Hulya CABADAK

ABSTRACT

Objective: The purpose of this study was to investigate if stimulating auto-paracrine muscarinic receptor signalling pathway could change human erythroleukemia K562 cell proliferation and caspase 3, 8 and 9 expression levels. To better understand the role of muscarinic receptors in cell signalling mechanism, we investigated the effects of several compounds on human erythroleukemia K562 cell proliferation and caspase 3, 8 and 9 expression. These compounds were M₃ muscarinic receptor agonist, pilocarpine, pro-inflammatory cytokine, tumor necrosis factor (TNF)-alpha, and the wortmannin which is a phosphoinositide 3-kinase inhibitor.

Materials and Methods: Cell proliferation and cell viability were evaluated by the trypan blue exclusion test and 5-Bromo-2-deoxy-uridine (BrdU) Labelling and Detection Kits. Caspase 3, 8 and 9 expression levels were determined by immunoblot analysis.

Results: Both pilocarpine and TNF-alpha caused a small increase in human erythroleukemia K562 cell proliferation. However, when all the compounds were treated together, proliferation of human erythroleukemia K562 cells increased significantly when compared to untreated control cells. TNF-alpha and wortmannin treatment increased caspase 3 and caspase 8 expression patterns significantly in human erythroleukemia K562 cells. TNF-alpha and wortmannin treatment increased caspase 9 expression level (P>0.05) but it was not significant.

Conclusion: These findings partly demonstrated that M₃ muscarinic receptor mediated an increase in K562 cell proliferation. Pilocarpine prevented TNF-alpha and wortmannin induced caspase 3 and 8 expression and indirectly showed apoptosis in human erythroleukemia K562 cells.

Keywords: M₃ muscarinic receptors, Cytokine, Pilocarpine, Caspases, Erythroleukemia K562 cells

Introduction

Chronic myelogenous leukemia (CML) which accounts for 20% of leukemia cases (annually 1-1.5/100.000 within a wide range of age width), is a malignant, clonal hematopoietic stem cell disorder [1]. Human erythroleukemia K562 cells derived from a 53-year-old female patient with CML in blast
Programmed cell death or apoptosis involves the activation of a series of cysteine aspartyl-specific proteases (caspases) related pathway and cell morphology changes. Caspase activation mechanisms are important in the apoptotic signalling pathway. During apoptosis two apoptotic pathways have been determined. These are cell-surface death receptor-dependent extrinsic pathway that activates caspase 8 and 10 and the other, the mitochondria-dependent intrinsic pathway that activates caspase 9. Both extrinsic and intrinsic pathways lead to changes in the caspase 3, 6 and 7 expression levels [10-11].

Tumor necrosis factor (TNF)-alpha has several roles in biological responses like stress response, cell proliferation, differentiation, apoptosis and inflammation [12]. TNF-alpha, is produced by the activated macrophages and by different types of cells. TNF-alpha can induce both pro- and anti-apoptotic signalling pathways. TNF-alpha binds to R1 and R2 subtypes of the TNF receptors. These receptors activate caspase 8 related pathway [13]. Previous studies showed that, TNF-alpha can trigger not only the cell death, but also cell survival pathway as well [14]. Wortmannin negatively regulates the PI3K/Akt pathway.

The aim of the present work was to investigate the role of M1 muscarinic receptor agonist pilocarpine on proliferation and caspase 3, 8 and 9 expression levels in K562 cells in a medium supplemented with 1% FBS after starvation. K562 cells were stimulated with pilocarpine in the presence or absence of other compounds in a medium supplemented with 1% FBS after starvation. We further investigated the effects of pro-inflammatory cytokine, TNF-alpha, the PI3-kinase inhibitor and wortmannin on cell proliferation in K562 cells. It remains unclear whether muscarinic M1 stimulation contributes to the effects produced against the pro-inflammatory cytokines like TNF-alpha and wortmannin.

Material and Methods

Cell line and antibodies were used in the study. K562 cells were purchased from the American Type Culture Collection (ATCC) (Rockville, MD). 5-Bromo-2-deoxy-uridine (BrdU) Labelling and Detection Kits were supplied from Roche Company (Mannheim, Germany). The antibodies were purchased from Santa Cruz Biotechnology Inc (Santa Cruz, CA, USA). Secondary antibodies were purchased from Sigma (St Louis, MO, USA). Pilocarpine, TNF-alpha and wortmannin were purchased from Sigma-Aldrich Company (St. Louis, MO). Pilocarpine was prepared as 100 mM stock in distilled water, filtered through 0.2 μm filter, and stored at –80°C. TNF-alpha was prepared as a 1 ng/ml solution in dimethyl sulfoxide (DMSO) and wortmannin was prepared as a 1 μM solution in DMSO.

Cell proliferation assay

Cells were seeded into cell culture dishes and cultured in Roswell Park Memorial Institute 1640 (RPMI-1640) medium supplemented with 2mM-L-glutamine, 1% heat-inactivated
FBS, 100 U/mL penicillin, 100 lg/mL streptomycin at 37 °C under a humidified condition of 95 % air and 5 % CO₂. Cell viability and proliferation were also evaluated by the trypan blue exclusion test and cell counter (TC-20 BioRad, Hercules, CA, USA). Live and dead cells were distinguished by trypan blue exclusion test. The cell proliferation assay was done by using a BrdU kit. BrdU kit protocol was described in our previous study [8]. 100 ml of passaged K562 cells (1×10⁶/cells) were seeded into 96 well plates containing RPMI-1640 medium without FBS. After 24 h, these “starved cells” were placed into a medium containing 1% FBS. The cells were grown in RPMI 1640 medium supplemented with 2 mM L-glutamine, 1% heat-inactivated FBS, 100 U/mL penicillin,100 lg/mL streptomycin, at 37 °C under a humidified condition of 95 % air and 5 % CO₂. One of the following was then added to TNF-alpha (1ng/ml), and /or wortmannin (1mM) and 30 min later pilocarpine (100 mM) was added and left for 24 h. K562 cells cultured in RPMI-1640 medium (Sigma, USA) containing 1% FBS in 5% CO₂ incubator at 37°C, constituted the control group.

**Preparation of whole-cell lysates and immunoblot analysis**

Cells were collected at 400 g and washed two times with phosphate buffered saline (PBS). The resulting pellets were resuspended and lyzed with 20 strokes in a hand dounce homogenizer in a buffer containing 20 mM Hepes-KOH, pH 8.0, 0.1 mM, ethylene diamine-tetraacetic acid (EDTA), 0.1mM phenylmethylsulfonyl fluoride, 10mg/mL leupeptin and 2 mg/mL aprotinin. The protein content of the whole lysates was determined by the method of Lowry et al. [15]. Immunoblot analyses were described in our previous studies with minor modification [9]. 100 mg of protein was used in immunoblots and blots incubated overnight at 4°C with antibodies against caspase 3, 8, 9 and b-actin in separate blots. Caspases 3, 8 and 9 were quantified versus b-actin on the blot. The apparent molecular weights of caspases 3, 8 and 9 were 11 kDa, 20 kDa, 46 kDa, respectively. The blots were analyzed by densitometry. Total amount of protein in each lane was normalized to the endogenous b-actin control. Densitometric analysis was carried out with the free edition of the Bio-Rad Molecular Analyst Software Program.

**Statistical analysis**

All figures show mean (SD) of at least six independent experiments. Statistically significant differences were determined by using the one-way analysis of variance followed by Dunnett’s post-tests. All statistical tests were performed with the Prism program (Graphpad Software) and (P<0.05) was considered significant. Asteriks were used to describe value levels of statistical significance (*P < 0.01; **P<0.003; ***P<0.003).

**Results**

Cells were stimulated with 100 µM pilocarpine, 1ng/ml TNF-alpha, 1 µM wortmannin for 24 h, and then cell viability and BrdU assay were carried out. The roles of M₁ muscarinic receptor agonist, pilocarpine, TNF-alpha, cytokine and PI3-kinase inhibitor and wortmannin, on proliferation of K562 cells are seen in (Figure 1). As shown in Figure 1, treatment of K562 cells with TNF-alpha in the absence of wortmannin had a minor stimulatory effect on BrdU incorporation (Figure 1), while treatment with (100 µM), TNF-alpha and wortmannin together had additive stimulatory effect on BrdU incorporation. When TNF-alpha and wortmannin were added in the absence of pilocarpine, the number of BrdU labeled cells increased to 19.59 ± 2.1% of the control. TNF-alpha, wortmannin and pilocarpine increased the number of BrdU-labeled cells to 22.30± 2.20 % of the control group. There was no significant difference between the group treated with pilocarpine and the control group in the medium supplemented with 1% FBS after starvation. The group treated with TNF-alpha + wortmannin on BrdU incorporation also increased cell proliferation but to a lesser degree when compared to the control group (P<0.05). Another group of cells that was treated with TNF-alpha+ pilocarpine + wortmannin on BrdU incorporation also increased significantly compared to the control group (P<0.05). The roles of M₁ muscarinic receptor agonist, pilocarpine, TNF-alpha, and PI3-kinase inhibitor, wortmannin on caspase 8, 9 protein expression in K562 cells were shown in figures 2 and 3. Inhibition of PI3K/Akt by wortmannin influenced the expression of caspase 8 overtly (Figure 2A) and caspase 3 (Figure 3). However, inhibition of PI3K had no effect on the expression of caspase 9 (Figure 2B). The increased caspase 3 expression induced by TNF-alpha and wortmannin was significantly attenuated by the addition of pilocarpine (Figure 3). These results suggested that pilocarpine could protect K562 cells from TNF-alpha and wortmannin induced apoptotic signalling pathway. We observed that combination of PI3KInhibitor, wortmannin and TNF-alpha increased expression of caspase 3, which is executioner or effector caspase and caspase 8, which is an initiator caspase (Figure 2A and Figure 3). Wortmannin specifically inhibited the phosphatidylinositol 3-kinase pathway, that could be used as a
promising apoptosis-based therapeutic agent with TNF-alpha in the treatment of leukemia. Flowchart about the mechanism involved in TNF-alpha and wortmannin mediated apoptosis in human erythroleukemia K562 cells was shown in Figure 4.

Figure 1. The effects of pilocarpine (100 mM) alone or in the presence of wortmannin (1μM), TNF-alpha (1ng/ml) on human erythroleukemia K562 cell proliferation. Cells (1×10^4 cells/well) were disseminated in 96 well dishes in the absence of fetal bovine serum and cultured for 24 h and then 1% fetal bovine serum was added with or without pilocarpine, wortmannin and TNF-alpha. The cells were pre-treated with wortmannin 30 min before addition of TNF-alpha. BrdU was applied for the last 4 h. Each bar represents the mean ±SEM of four independent experiments. *P<0.05 between control versus TNF-alpha+wortmannin, TNF-alpha +pilocarpine +wortmannin

Figure 2. The effect of pilocarpine on the expression of caspase 8 and 9 proteins. K562 cells were treated with wortmannin (1 μM) for 30 min prior to exposure to TNF-alpha (1ng/ml) and / or pilocarpine. Western blot analysis for expression of caspase 8 and 9 was performed on whole lysates. (A) Apoptosis initiating protein levels of caspase 8 (20 kDa) and (B) caspase 9 (46 kDa) were detected by Western blotting. ß-Actin was used to normalize the amount of protein loaded in each lane. Representative Western blot images are shown. Values are expressed as the mean ± SEM of four independent experiments. *P<0.003; **P<0.01.

Figure 3. The effect of pilocarpine on the expression of caspase 3 protein. K562 cells were treated with wortmannin (1 μM) for 30 min prior to the exposure of TNF-alpha (1ng/ml) with or without pilocarpine (100 μM). Western blot analyses for expression of caspase 3 were performed on whole lysates. Apoptosis effector protein of caspase 3 (11 kDa) was detected by Western blotting. ß-Actin was used to normalize the amount of protein loaded in each lane. Values are expressed as the mean± SEM of four independent experiments. *P<0.003; **P<0.01; ***P<0.003.

Figure 4. Schematic representation of the mechanism involved in TNF-alpha and wortmannin mediated expression of caspase 3, 8 and 9 during apoptosis of human erythroleukemia K562 cells.
These findings indicate that pilocarpine may act through M₃₅R signaling to prevent apoptosis and promote erythroleukemia cell proliferation, targeting that M₃₅R, PI3K and TNF-alpha might provide us a potential therapeutic strategy for leukemia treatment.

Discussion

In the present study, we have demonstrated the effects of TNF-alfa, pilocarpine and wortmannin on the cell proliferation and caspase 3, 8 and 9 expression levels in human erythroleukemia K562 cells. M₃ muscarinic receptor is expressed in different cancer types. These cancer types are the skin, colon, gastric, pancreatic, breast, ovarian, brain and lung [16]. TNF-alpha, produced by activated macrophages, is a cytokine that influences growth, differentiation and apoptosis in most cell types [17]. Different researchers suggested that TNF-alpha could also trigger cell survival pathway that induced NFkB pathway [18]. It was also documented that caspase 3 and 8 may have been the key regulators of the apoptotic response during tumorigenesis [19]. González-Flores and colleagues showed that TNF-alpha caused a time dependent increase in caspase 3, 8 and 9 activities in K562 cells [18]. Another group detected similar results in U937 cells [20] but in their study they used different FBS concentration in the cell proliferation medium. Sandra and colleagues showed that a low concentration of TNF-alpha in the presence of wortmannin or LY294002 induced apoptosis in a human head and neck squamous cell carcinoma (SAS) cell line. They suggested that the PI3K-NFkB pathway contributed to the TNF-alpha induced cell survival and that inhibition of this pathway accelerated apoptosis in the SAS cell line [21]. Various researchers showed that PI3K/Akt pathway could inhibit cell apoptosis [22, 23]. PI3K/Akt pathway is also involved in both proliferation and inhibition of apoptosis. It was also demonstrated that the cell proliferation could be evidently inhibited by wortmannin in a dose-dependent manner and wortmannin could arrest the cell cycle and induce cell apoptosis. It was also stated that, a lower concentration of wortmannin did not induce apoptosis [24]. Previously, we had shown that the PI3-kinase inhibitor wortmannin (1 µM) had an inhibitory effect on DNA synthesis. But, DNA synthesis was stimulated when wortmannin was added prior to CCh challenge. We also suggested that different signalling pathways participated in the muscarinic receptor mediated regulation of cell proliferation in one of our previous studies [9]. Exogenous muscarinic agonist, pilocarpine stimulated cell growth in non-small cell lung cancer (NSCLC) A549 and PC9 cell lines but M₃ muscarinic antagonist, methoctramine inhibited tumor growth [25]. This study showed that pilocarpine caused a little increase in K562 cell proliferation when compared to the control group, while TNF-alpha and wortmannin had additive effects in increasing K562 cell proliferation in 24 h. TNF-alpha, pilocarpine and wortmannin together increased K562 cell proliferation when compared to the control group. The intracellular pathway compounds had biological effects on these cells. Our results led us to conclude that pilocarpine could protect cells from apoptosis. In the present study, when TNF-alpha, PI3K inhibitor and wortmannin were administered together, they induced apoptosis which involved pathways of receptor-mediated apoptosis. But, they did not affect the mitochondrial pathway in K562 cells. As shown, in this study TNF-alpha and wortmannin induced apoptosis via caspase 8 which initiated receptor-mediated apoptosis, but TNF-alpha and wortmannin did not affect caspase 9, mitochondrial cell death pathway in K562 cells, significantly.

Our study suggested that the treatment of human erythroleukemia K562 cells with TNF-alpha and wortmannin induced caspase 3 and 8 expression in the absence of pilocarpine. But, addition of pilocarpine decreased caspase 3 and 8 expression within 24 h in K562 cells. Our results implied an indirect contribution to the apoptotic pathway in human erythroleukemia cells, since we only detected caspase 3, 8 and 9 protein levels. Finally, we provided a flowchart about the mechanisms involved in TNF-alpha and wortmannin mediated apoptotic pathway proteins for the protective effects of pilocarpine in human erythroleukemia K562 cells. M₃ receptor-mediated suppression of TNF-alpha and wortmannin effects may be important protective mechanisms of apoptosis in the erythroleukemia cells.

In conclusion, our results suggested that TNF-alpha and wortmannin together stimulated caspase 3, 8 expression and finally increased apoptosis in human erythroleukemia cells.

Pilocarpine prevented TNF-alpha and wortmannin induced apoptotic protein and expression of caspase 3 and 8 in K562 cells, resulting in the inhibition of TNF-alpha and wortmannin mediated caspase expression. We hypothesize that this may protect human erythroleukemia cells from apoptosis. The suppressive effect of pilocarpine was further demonstrated by the decreased expression of caspase 3, which acted as an essential executor and expression of caspase 8, a biomarker of apoptosis in mammalian cells, which initiated
receptor-mediated apoptosis. Our findings may partly explain the mechanisms underlying the protective effect of M₄ muscarinic receptors in apoptosis. The involvement of M₄-muscarinic receptors in the protection of cell death induced by TNF-alpha and wortmannin was supported by the up-regulation of PI3K pathway.

In summary, pilocarpine via M₄ muscarinic receptor appeared to have an inhibitory function and could be regarded as an important mediator in TNF-alpha and wortmannin mediated erythroleukemia cell apoptosis.

Compliance with ethical standards: Ethical approval is not needed (Cell line culture). K562 cells were purchased from the American Type Culture Collection (ATCC) (Rockville, MD).

Conflict of Interest: The authors declare that there is no conflict of interest regarding the publication of this manuscript.
